

COMP6771

Advanced C++ Programming

Week 8.1

Advanced Templates

Default Members

```
1 #include <vector>
2
3 template<typename T, typename CONT = std::vector<T>>
4 class stack {
5 public:
6     stack();
7     ~stack();
8     auto push(T&) -> void;
9     auto pop() -> void;
10    auto top() -> T&;
11    auto top() const -> T const&;
12    static int num_stacks_;
13
14 private:
15     CONT stack_;
16 };
17
18 template<typename T, typename CONT>
19 int stack<T, CONT>::num_stacks_ = 0;
20
21 template<typename T, typename CONT>
22 stack<T, CONT>::stack() {
23     num_stacks_++;
24 }
25
26 template<typename T, typename CONT>
27 stack<T, CONT>::~stack() {
28     num_stacks_--;
29 }
```

demo801-default.h

- We can provide default arguments to template types (where the defaults themselves are types)
- It means we have to update all of our template parameter lists.
- The set of default template arguments accumulates over all declarations of a given template.

```
1 #include <iostream>
2
3 #include "./demo801-default.h"
4
5 auto main() -> int {
6     auto fs = stack<float>{};
7     stack<int> is1, is2, is3;
8     std::cout << stack<float>::num_stacks_ << "\n";
9     std::cout << stack<int>::num_stacks_ << "\n";
10    auto fl = stack<float, std::list<float>>{};
11 }
```

demo801-default.cpp

```
1 template<class T, class U = int> class A;
2 template<class T = float, class U> class A;
3
4 template<class T, class U> class A {
5     public:
6         T x;
7         U y;
8 };
9
10 A<> a;
11 a.x ?
12 a.y?
```

```
1 template<class T, class U = char> class A
2 {
3     public:
4         T x;
5         U y;
6     };
7
8 int main()
9 {
10     A<char> a;
11     A<int, int> b;
12     std::cout<<sizeof(a)<<std::endl;
13     std::cout<<sizeof(b)<<std::endl;
14     return 0;
15 }
```

If one template parameter has a default argument, then all template parameters following it must also have default arguments.

```
1 template<class T = char, class U, class V = int> class X { };
2
3 template<class T = char, class U, class V = int, class W> class X
4 //not allowed
```

Specialisation

- The templates we've defined so far are completely generic
- There are two ways we can redefine our generic types for something more specific:
 - Partial specialisation:
 - Describing the template for another form of the template
 - T^*
 - `std::vector<T>`
 - Explicit specialisation:
 - Describing the template for a specific, non-generic type
 - `std::string`
 - `int`

When to specialise

- You need to preserve existing semantics for something that would not otherwise work
 - `std::is_pointer` is partially specialised over pointers
- You want to write a type trait
 - `std::is_integral` is fully specialised for `int`, `long`, etc.
- There is an optimisation you can make for a specific type
 - `std::vector<bool>` is fully specialised to reduce memory footprint

When **not** to specialise

- Don't specialise functions
 - A function cannot be partially specialised
 - Fully specialised functions are better done with overloads
 - Herb Sutter has an article on this
 - <http://www.gotw.ca/publications/mill17.htm>
- You think it would be cool if you changed some feature of the class for a specific type
 - People assume a class works the same for all types
 - Don't violate assumptions!

Our Template

- Here is our stack template class
 - stack.h
 - stack_main.cpp

```
1 #include <vector>
2 #include <iostream>
3 #include <numeric>
4
5 template <typename T>
6 class stack {
7 public:
8     auto push(T t) -> void { stack_.push_back(t); }
9     auto top() -> T& { return stack_.back(); }
10    auto pop() -> void { stack_.pop_back(); }
11    auto size() const -> int { return stack_.size(); }
12    auto sum() -> int {
13        return std::accumulate(stack_.begin(), stack_.end(), 0);
14    }
15 private:
16     std::vector<T> stack_;
17 };
```

```
1 auto main() -> int {
2     int i1 = 6771;
3     int i2 = 1917;
4
5     stack<int> s1;
6     s1.push(i1);
7     s1.push(i2);
8     std::cout << s1.size() << " ";
9     std::cout << s1.top() << " ";
10    std::cout << s1.sum() << "\n";
11 }
```

Partial Specialisation

- In this case we will specialise for pointer types.
 - Why do we need to do this?
- You can partially specialise classes
 - You cannot partially specialise a particular function of a class in isolation
- The following a fairly standard example, for illustration purposes only. Specialisation is designed to refine a generic implementation for a specific type, not to change the semantic.

```
1 template <typename T>
2 class stack<T*> {
3 public:
4     auto push(T* t) -> void { stack_.push_back(t); }
5     auto top() -> T* { return stack_.back(); }
6     auto pop() -> void { stack_.pop_back(); }
7     auto size() const -> int { return stack_.size(); };
8     auto sum() -> int{
9         return std::accumulate(stack_.begin(),
10             stack_.end(), 0, [] (int a, T *b) { return a + *b; });
11     }
12 private:
13     std::vector<T*> stack_;
14 }
```

demo802-partial.h

```
1 #include "./demo802-partial.h"
2
3 auto main() -> int {
4     auto i1 = 6771;
5     auto i2 = 1917;
6     auto s1 = stack<int>{};
7     s1.push(i1);
8     s1.push(i2);
9     std::cout << s1.size() << " ";
10    std::cout << s1.top() << " ";
11    std::cout << s1.sum() << "\n";
12
13 }
```

demo802-partial.cpp

```
1 auto s2 = stack<int*>{};
2 s2.push(&i1);
3 s2.push(&i2);
4 std::cout << s2.size() << " ";
5 std::cout << *(s2.top()) << " ";
6 std::cout << s2.sum() << "\n";
```

Explicit Specialisation

```
1 #include <iostream>
2
3 template <typename T>
4 void fun(T a) {
5     std::cout << "The main template fun(): "
6             << a << std::endl;
7 }
8
9 template<> // may be skipped, but prefer overloads
10 void fun(int a) {
11     std::cout << "Explicit specialisation for int type: "
12             << a << std::endl;
13 }
14
15 int main() {
16     fun<char>('a');
17     fun<int>(10);
18     fun<float>(10.14);
19 }
```

```
1 #include<iostream>
2 #include<sstream>
3 #include<vector>
4
5 template<typename T>
6 T add_all(const std::vector<T> &list) {
7     T accumulator = {};
8     for (auto& elem:list){
9         accumulator += elem;
10    }
11
12    return accumulator;
13 }
14
15 template<>
16 T add_all(const std::vector<std::string> &list) {
17     std::string accumulator = {};
18     for (const std::string& elem : list)
19         for (const char& chr : elem)
20             accumulator += elem;
21    }
22
23    return accumulator;
24 }
25
26 int main() {
27     std::vector<int> ivec = {4,3,2,4};
28     std::vector<double> dvec = {4.0,3.0,2.0,4.0};
29     std::vector<string> svec = {"abc", "bcd"};
30     std::cout << add_all(ivec) << std::endl;
31     std::cout << add_all(dvec) << std::endl;
32     std::cout << add_all(svec) << std::endl;
33 }
```

Class Template Specialisation

```
1 #include <iostream>
2
3 template <class T>
4 class Test {
5 // Data members of test
6 public:
7     Test() {
8         // Initialization of data members
9         cout << "General template object \n";
10    }
11
12    // Other methods of Test
13 };
14
15 template <>
16 class Test<int> {
17 public:
18     Test() {
19         // Initialization of data members
20         std::cout << "Class template specialisation\n";
21     }
22 };
23
24 int main() {
25     Test<int> a;
26     Test<char> b;
27     Test<float> c;
28
29     return 0;
30 }
```

Explicit Specialisation

- Explicit specialisation should only be done on classes.
- `std::vector<bool>` is an interesting example and [here](#) too
 - `std::vector<bool>::reference` is not a `bool&`

```
1 #include <iostream>
2
3 template <typename T>
4 struct is_void {
5     static bool const val = false;
6 };
7
8 template<>
9 struct is_void<void> {
10     static bool const val = true;
11 };
12
13 auto main() -> int {
14     std::cout << is_void<int>::val << "\n";
15     std::cout << is_void<void>::val << "\n";
16 }
```

demo803-explicit.cpp

Type Traits

Trait: Class (or class template) that *characterises* a type

Compile time template metafunctions that returns the info about types.

Ask compiler some question? is it int, fun, class or pointer or will it throw exception?

Why ?: **Optimization: quick sort /merge sort by knowing data type of iterator or const to non**
type trait is a simple struct template that contains a member constant, which in turn holds the answer to the question the type trait asks or the transformation it performs

Useful in conditional compilation or
you can apply transformation i.e. add or remove const
handy when writing libraries that make use of template

Advantage: All at compile time, nothing run time

Trait Categoris:

Numeric_Limit<>:: min,max, is_signed, is_integer

Type Category: **is_array<T>::value**, **is_pointer**, **is_enum**

Type Properties: **is_const**

```
1 #include <iostream>
2 #include <limits>
3
4 auto main() -> int {
5     std::cout << std::numeric_limits<double>::min() << "\n";
6     std::cout << std::numeric_limits<int>::min() << "\n";
7 }
8
9 template <typename T>
10 struct numeric_limits {
11     static auto min() -> T;
12 };
13
14 template <>
15 struct numeric_limits<int> {
16     static auto min() -> int { return -INT_MAX - 1; }
17 }
18
19 template <>
20 struct numeric_limits<float> {
21     static auto min() -> float { return -FLT_MAX - 1; }
22 }
```

This is what <limits> might look like

Type Traits

Traits allow generic template functions to be parameterised

```
1 #include <array>
2 #include <iostream>
3 #include <limits>
4
5 template<typename T, std::size_t size>
6 T findMax(const std::array<T, size>& arr) {
7     T largest = std::numeric_limits<T>::min();
8     for (auto const& i : arr) {
9         if (i > largest)
10             largest = i;
11     }
12     return largest;
13 }
14
15 auto main() -> int {
16     auto i = std::array<int, 3>{-1, -2, -3};
17     std::cout << findMax<int, 3>(i) << "\n";
18     auto j = std::array<double, 3>{1.0, 1.1, 1.2};
19     std::cout << findMax<double, 3>(j) << "\n";
20 }
```

```
1 #include <type_traits>
2
3 class GFG {
4 };
5
6 // main method
7 auto main() -> int {
8 {
9     std::cout << alignment_of<GFG>::value << std::endl;
10    std::cout << alignment_of<int>() << std::endl;
11    std::cout << alignment_of<double>() << std::endl;
12
13    return 0;
14 }
```

demo804-typetraits1.cpp

Two more examples

- Below are STL type trait examples for a specialisation and partial specialisation
- This is a good example of partial specialisation
- http://en.cppreference.com/w/cpp/header/type_traits

```
1 #include <iostream>
2
3 template <typename T>
4 struct is_void {
5     static const bool val = false;
6 };
7
8 template<>
9 struct is_void<void> {
10    static const bool val = true;
11 };
12
13 auto main() -> int {
14     std::cout << is_void<int>::val << "\n";
15     std::cout << is_void<void>::val << "\n";
16 }
```

demo805-typetraits2.cpp

```
1 #include <iostream>
2
3 template <typename T>
4 struct is_pointer {
5     static const bool val = false;
6 };
7
8 template<typename T>
9 struct is_pointer<T*> {
10    static const bool val = true;
11 };
12
13 auto main() -> int {
14     std::cout << is_pointer<int*>::val << "\n";
15     std::cout << is_pointer<int>::val << "\n";
16 }
```

demo806-typetraits3.cpp

```
1 template<template T>
2 typename std::remove_reference<T>::
3 {return value;}
```

const T&	const T	
T &	T	
T&&	T	do more than conversion
const T	T	

Where it's useful

- Below are STL type trait examples
- http://en.cppreference.com/w/cpp/header/type_traits

```
1 #include <iostream>
2 #include <type_traits>
3
4 template<typename T>
5 auto testIfNumberType(T i) -> void {
6     if (std::is_integral<T>::value || std::is_floating_point<T>::value) {
7         std::cout << i << " is a number"
8             << "\n";
9     }
10 else {
11     std::cout << i << " is not a number"
12             << "\n";
13 }
14
15 auto main() -> int {
16     auto i = int{6};
17     auto l = long{7};
18     auto d = double{3.14};
19     testIfNumberType(i);
20     testIfNumberType(l);
21     testIfNumberType(d);
22     testIfNumberType(123);
23     testIfNumberType("Hello");
24     auto s = "World";
25     testIfNumberType(s);
26 }
```

demo807-typetraits4.cpp

```
1 #include <iostream>
2 #include <type_traits>
3
4 void algorithm_signed (int i)      { /*...*/ }
5 void algorithm_unsigned(unsigned u) { /*...*/ }
6
7 template <typename T>
8 void algorithm(T t) // act as dispatcher
9 {
10     if constexpr(std::is_signed<T>::value)
11         algorithm_signed(t);
12     else
13         if constexpr (std::is_unsigned<T>::value)
14             algorithm_unsigned(t);
15     else
16         static_assert(std::is_signed<T>::value
17                         || std::is_unsigned<T>::value, "Must be signed or unsigned!");
18
19 }
20
21 int main(){
22     algorithm(3);           // T is int, include algorithm_signed()
23     algorithm(3);           // T is int, include algorithm_unsigned()
24     unsigned x = 3;
25     algorithm(x);          // T is unsigned int, include algorithm_unsigned()
26
27     algorithm("hello");    // T is string, build error!
28 }
```

Variadic Templates

These are the instantiations that will have been generated

```
1 #include <iostream>
2 #include <typeinfo>
3
4 template <typename T>
5 auto print(const T& msg) -> void {
6     std::cout << msg << " ";
7 }
8
9 template <typename A, typename... B>
10 auto print(A head, B... tail) -> void {
11     print(head);
12     print(tail...);
13 }
14
15 auto main() -> int {
16     print(1, 2.0f);
17     std::cout << "\n";
18     print(1, 2.0f, "Hello");
19     std::cout << "\n";
20 }
```

demo808-variadic.cpp

```
1 auto print(const char* const& c) -> void {
2     std::cout << c << " ";
3 }
4
5 auto print(float const& b) -> void {
6     std::cout << b << " ";
7 }
8
9 auto print(float b, const char* c) -> void {
10     print(b);
11     print(c);
12 }
13
14 auto print(int const& a) -> void {
15     std::cout << a << " ";
16 }
17
18 auto print(int a, float b, const char* c) -> void {
19     print(a);
20     print(b, c);
21 }
```

Title Text

Subtitle

```
1 #include <iostream>
2 #include <typeinfo>
3
4
5 template <typename A, typename... B>
6 auto print(A head, B... tail) -> void {
7     std::cout << head;
8     print(tail...);
9 }
10
11 auto main() -> int {
12     print(1, 2.0f);
13     std::cout << "\n";
14     print(1, 2.0f, "Hello");
15     std::cout << "\n";
16 }
```

Member Templates

- Sometimes templates can be too rigid for our liking:
 - Clearly, this *could* work, but doesn't by default

```
1 #include <vector>
2
3 template <typename T>
4 class stack {
5 public:
6     auto push(T& t) -> void { stack_.push_back(t); }
7     auto top() -> T& { return stack_.back(); }
8 private:
9     std::vector<T> stack_;
10 };
11
12 auto main() -> int {
13     auto is1 = stack<int>{};
14     is1.push(2);
15     is1.push(3);
16     auto is2 = stack<int>{is1}; // this works
17     auto ds1 =
18         stack<double>{is1}; // this does not
19 }
```

Member Templates

Through use of member templates, we can extend capabilities

```
1 #include <vector>
2
3 template <typename T>
4 class stack {
5 public:
6     explicit stack() {}
7     template <typename T2>
8     stack(stack<T2>&); // This is a member template
9     auto push(T t) -> void { stack_.push_back(t); }
10    auto pop() -> T;
11    auto empty() const -> bool { return stack_.empty(); }
12 private:
13     std::vector<T> stack_;
14 };
15
16 template <typename T>
17 T stack<T>::pop() {
18     T t = stack_.back();
19     stack_.pop_back();
20     return t;
21 }
22
23 template <typename T>
24 template <typename T2>
25 stack<T>::stack(stack<T2>& s) {
26     while (!s.empty()) {
27         stack_.push_back(static_cast<T>(s.pop()));
28     }
29 }
```

```
1 auto main() -> int {
2     auto is1 = stack<int>{};
3     is1.push(2);
4     is1.push(3);
5     auto is2 = stack<int>{is1}; // This works
6     auto ds1 =
7         stack<double>{is1}; // This does not work
8     // Until we do the changes on the left
9 }
```

Template Template Parameters

```
1 template <typename T, template <typename> typename CONT>
2 class stack { }
```

- Previously, when we want to have a Stack with templated container type we had to do the following:
 - What is the issue with this?

```
1 #include <iostream>
2 #include <vector>
3
4 auto main(void) -> int {
5     stack<int, std::vector<int>> s1;
6     s1.push(1);
7     s1.push(2);
8     std::cout << "s1: " << s1 << "\n";
9
10    stack<float, std::vector<float>> s2;
11    s2.push(1.1);
12    s2.push(2.2);
13    std::cout << "s2: " << s2 << "\n";
14    //stack<float, std::vector<int>> s2; :0
15 }
```

Ideally we can just do:

```
1 #include <iostream>
2 #include <vector>
3
4 auto main(void) -> int {
5     stack<int, std::vector> s1;
6     s1.push(1);
7     s1.push(2);
8     std::cout << "s1: " << s1 << std::endl;
9
10    stack<float, std::vector> s2;
11    s2.push(1.1);
12    s2.push(2.2);
13    std::cout << "s2: " << s2 << std::endl;
14 }
```

Template Template Parameters

```
1 #include <iostream>
2 #include <vector>
3
4 template <typename T, typename Cont>
5 class stack {
6 public:
7     auto push(T t) -> void { stack_.push_back(t); }
8     auto pop() -> void { stack_.pop_back(); }
9     auto top() -> T& { return stack_.back(); }
10    auto empty() const -> bool { return stack_.empty(); }
11 private:
12     CONT stack_;
13 };
```

```
1 #include <iostream>
2 #include <vector>
3 #include <memory>
4
5 template <typename T, template <typename...> typename CONT>
6 class stack {
7 public:
8     auto push(T t) -> void { stack_.push_back(t); }
9     auto pop() -> void { stack_.pop_back(); }
10    auto top() -> T& { return stack_.back(); }
11    auto empty() const -> bool { return stack_.empty(); }
12 private:
13     CONT<T> stack_;
14 };
```

```
1 auto main(void) -> int {
2     stack<int, std::vector<int>> s1;
3     int i1 = 1;
4     int i2 = 2;
5     s1.push(i1);
6     s1.push(i2);
7     while (!s1.empty()) {
8         std::cout << s1.top() << " ";
9         s1.pop();
10    }
11    std::cout << "\n";
12 }
```

```
1 #include <iostream>
2 #include <vector>
3
4 auto main(void) -> int {
5     auto s1 = stack<int, std::vector>{};
6     s1.push(1);
7     s1.push(2);
8 }
```

- When compiler tries to find a template to match the template template argument, it only considers primary class templates.
- (A *primary template* is the template that is being specialized.) The compiler will not consider any partial specialization even if their parameter lists match that of the template template parameter.

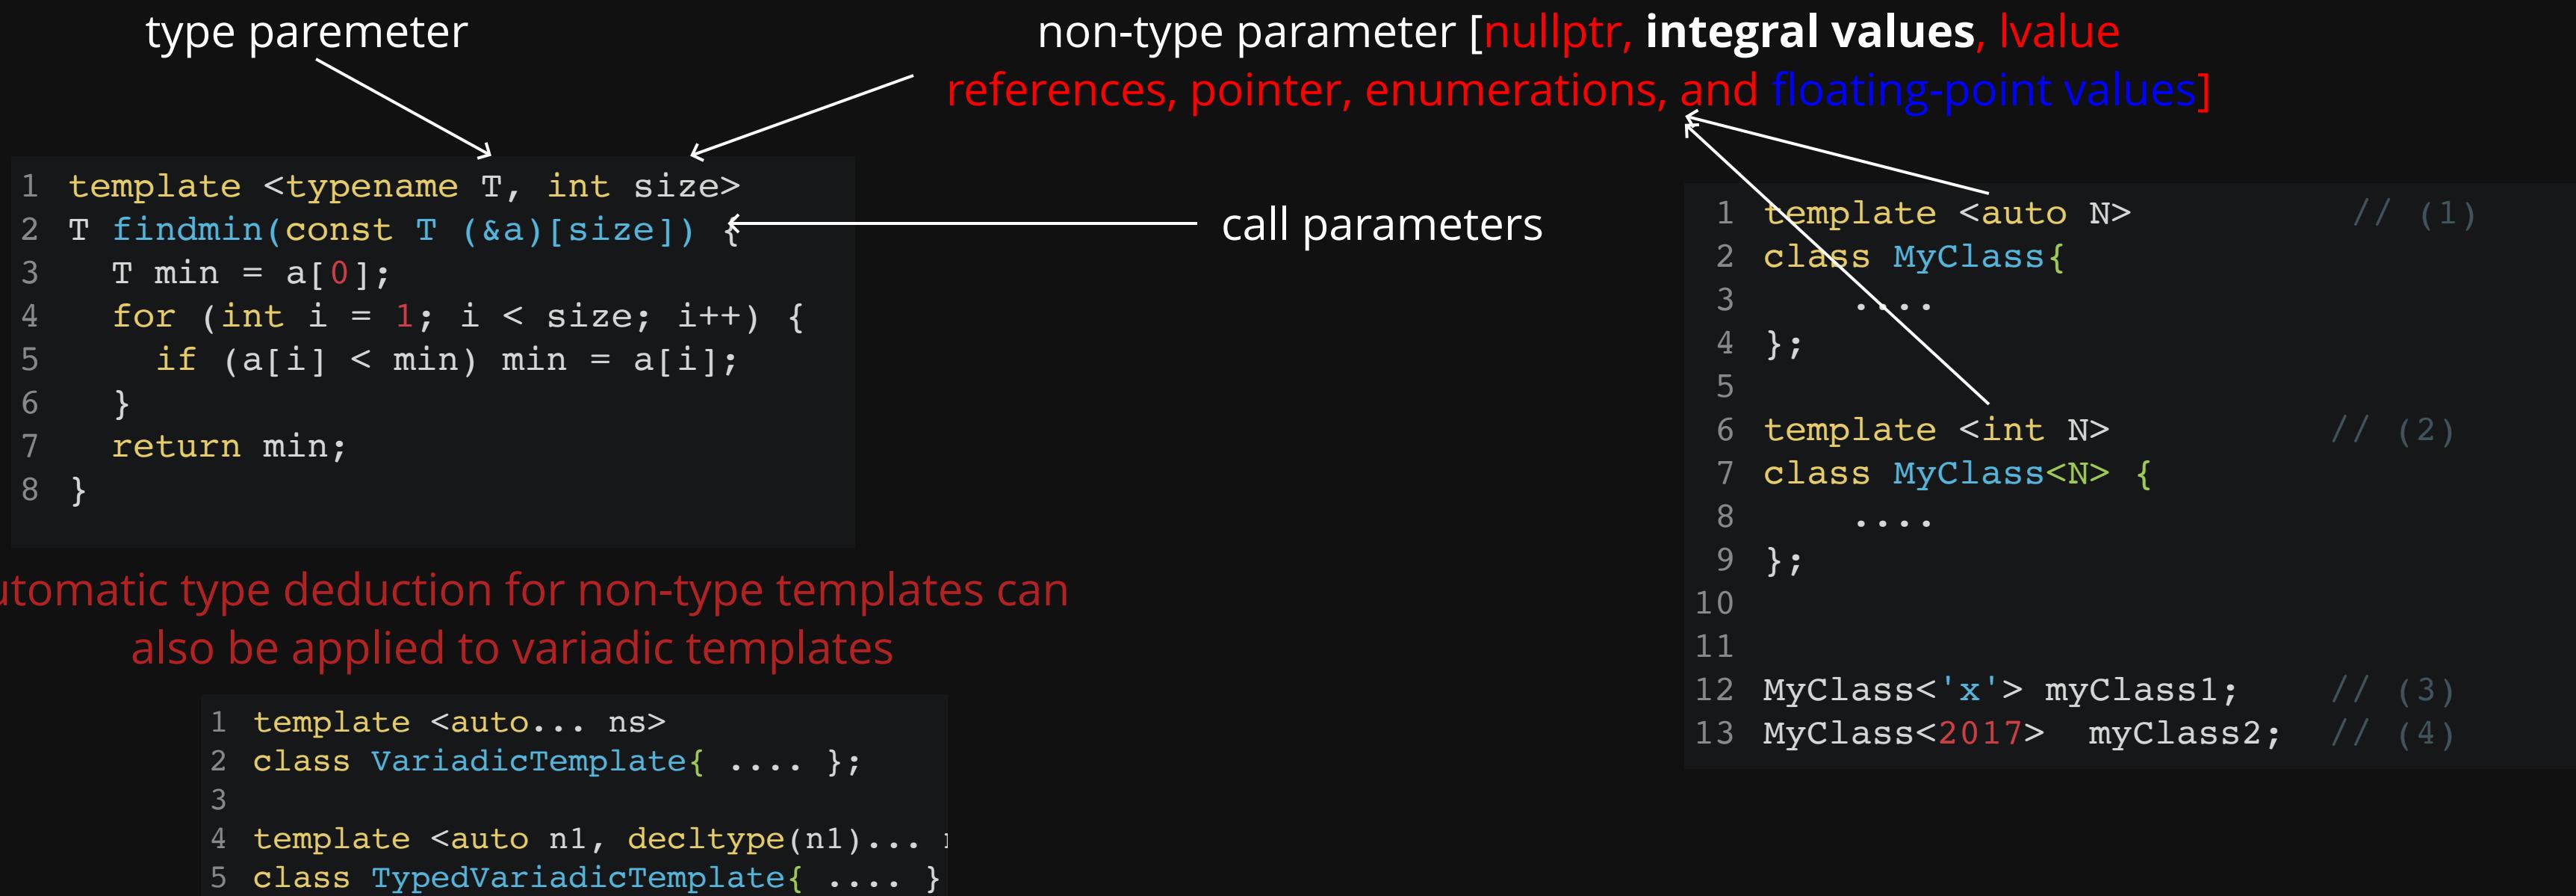

```
1 #include <vector>
2 #include <iostream>
3
4 template <class T, template <class...> class C, class U>
5 C<T> All_V(const C<U> &c) {
6     C<T> result(c.begin(), c.end());
7     return result;
8 }
9
10 int main() {
11     std::vector<float> vf = {1.2, 2.6, 3.7};
12     auto vi = All_V<int>(vf);
13     for(auto &&i: vi) {
14         std::cout << i << std::endl;
15     }
16 }
```

The compiler considers the partial specializations based on a template template argument once you have instantiated a specialization based on the corresponding template template parameter.

Template Argument Deduction

Template Argument Deduction is the process of determining the types (of **type parameters**) and the values of **nontype parameters** from the types of **function arguments**.

```
1 std::vector<int> v{1,2,3};  
2 std::vector v{1,2,3};
```

Implicit Deduction

- We may omit any template argument that the compiler can determine or deduce by the usage and context of that template function call.
- The compiler tries to deduce a template argument by comparing the type of the corresponding template parameter with the type of the argument used in the function call.
The two types that the compiler compares (the template parameter and the argument used in function call) must be of certain structure in order for template argument deduction to work.
- Non-type parameters: Implicit conversions behave just like normal type conversions
- Type parameters: Three possible implicit conversions
- ... others as well, that we won't go into

```
1 f(1,2); // f<int>(1,2);
2 f(1.1,2.2); f<double>(1.1,2.2);
3 f('a', 'b'); f<char>(char a, char b);
4 f(2, 'b'); ?
5 f(2, 2.2); ? ?
6
7 //
8 template<typename T>
9   T f(T a, T b)
10    return a+b;
11
12 template<typename T1, typename T2>
13   T f(T1 a, T2 b)
14    return a+b;
15
```

```
1 // array to pointer
2 template <typename T>
3 f(T* array) {}
4
5 int a[] = { 1, 2 };
6 f(a);

1 // const qualification
2 template <typename T>
3 f(const T item) {}
4
5 int a = 5;
6 f(a); // int => const int;
```

```
1 // conversion to base class
2 // from derived class
3 template <typename T>
4 void f(base<T> &a) {}
5
6 template <typename T>
7 class derived : public base<T> { }
8 derived<int> d;
9 f(d);
```

Explicit Deduction

If we need more control over the normal deduction process, we can explicitly specify the types being passed in

- casting the argument to follow same type
- explicitly stating type of T, preventing compiler attempting to deduce
- specifying in function template that parameter may be of different type and let it on compiler to figure it out.

```
1 template<typename T>
2 T min(T a, T b) {
3     return a < b ? a : b;
4 }
5
6 auto main() -> int {
7     auto i = int{0};
8     auto d = double{0};
9     min(i, static_cast<int>(d)); // int min(int, int)
10    // min<int>(i, d); // int min(int, int)
11    min(static_cast<double>(i), d); // double min(double, double)
12    min<double>(i, d); // double min(double, double)
13 }
```
